## SOIL HEALTH

100.0/  
100

**Excellent**

All measured parameters are currently within the defined optimal ranges.

## MEASURED SOIL PARAMETERS

| Parameter                    | Value       | Status  |
|------------------------------|-------------|---------|
| pH                           | 6.8         | Optimal |
| Nitrogen (N)                 | 180.0 kg/ha | Optimal |
| Phosphorus (P)               | 45.0 kg/ha  | Optimal |
| Potassium (K)                | 220.0 kg/ha | Optimal |
| Electrical Conductivity (EC) | 0.65 dS/m   | Optimal |
| Soil Moisture                | 24.0 %      | Optimal |
| Soil Temperature             | 28.0 °C     | Optimal |
| Organic Carbon               | 0.75 %      | Optimal |

## CROP RECOMMENDATIONS

| Crop      | Suitability | Season                  | Notes                                                                                                                                                                                                                                                            |
|-----------|-------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Maize     | 61.2%       | Kharif (Jun–Jul sowing) | Makka (maize) is a good choice for your soil. Sow after first rain in June–July. Water regularly — do not let soil dry out. Harvest in about 3.5 months. Apply Urea in two parts: half at sowing, half when plant is knee-high.                                  |
| Cotton    | 17.7%       | Kharif (Apr–May sowing) | Kapas (cotton) can grow in your soil. Sow in April–May. Needs regular watering every 10–15 days. Picking starts after about 5 months. Apply NPK 120:60:60 kg/ha. Watch for bollworm pest — spray if needed.                                                      |
| Pigeonpea | 6.3%        | Kharif (Jun–Jul sowing) | Arhar/Tur (pigeonpea) has deep roots and suits your soil well. Sow at start of monsoon. Drought-tolerant — survives dry spells. Fixes nitrogen in soil — good to grow before a cereal crop. Apply only 20 kg Urea per acre; too much nitrogen reduces pod count. |
| Wheat     | 5.8%        | Rabi (Oct–Nov sowing)   | Gehun (wheat) grows well in your soil. Sow in October–November. Water 5–6 times during the season. Ready to cut in about 4 months. Use Urea and DAP fertilizer at sowing time for good yield.                                                                    |
| Rice      | 3.9%        | Kharif (Jun–Jul sowing) | Chawal (rice/paddy) suits your soil. Needs good water supply — keep field flooded in early weeks. Transplant seedlings after 25–30 days in nursery. Ready in about 4 months. Use DAP at transplanting and Urea 20 days after transplanting.                      |

## FERTILIZER RECOMMENDATIONS

| Recommendation | Type      | Dose                                      | Notes                                                                                                                                                                                                                                                                                                                         |
|----------------|-----------|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Balanced NPK   | inorganic | See dose details in the description below | Your soil needs all three nutrients — Nitrogen (N), Phosphorus (P), and Potassium (K). Buy NPK 10:26:26 or NPK 12:32:16 bag from your nearest input shop. Apply 1 bag (50 kg) per acre at sowing time, mixed into the soil before planting. Also add 1 bag of Urea (45 kg) in two splits: half at sowing, half 30 days later. |

## DECISION-SUPPORT NOTICE

The analysis above is an indicative screening based on published range thresholds for Indian agricultural conditions. Values and recommendations should be confirmed with a certified soil testing laboratory or local agricultural officer before making input decisions.
